

Name _____ Surname _____ Date ____/____/____

Estimate, then measure

Step 1 — before you touch any instrument, estimate a quantity by eye.

Step 2 — measure it for real. Fill in the class value together at the end.

You can measure the same quantity more than once, on different objects and with different instruments: use as many rows as you like.

Ideas for what you could measure

the mass of a pen · the thickness of a pen · the length of a chair · the lap time of the animation on the board · the fall time of a pen dropped from about one metre · the circumference of a bottle or a cup (this one is tricky to guess by eye) · or anything else you're curious about, as long as it's a length, a mass, or a time

Ideas for how to estimate, before measuring

count seconds in your head ("one-Mississippi, two-Mississippi...") · use hand spans, finger widths, foot-lengths or arm spans for length · compare a mass to something you already know well, like a phone, an apple, or a coin

Counting seconds without a stopwatch

Say "one-Mississippi, two-Mississippi, three-Mississippi..." instead of just "one, two, three...". Saying the full word "Mississippi" takes about one second, so each "number-Mississippi" is roughly one second. It won't be perfectly accurate — everyone says it at a slightly different speed — but it's much closer than just counting numbers, which people tend to rush.

[illegible]
